

## **CONSENT FOR EXAMINATION**

Caverject is injected in the cavernous part of the penis in order to assess the vascular cause of erectile dysfunction. The medicinal product stimulates the relaxation of smooth muscles of arteries, which causes erection when the blood inflow is sufficient.

Caverject is also suitable for self-injection.

During the examination, the dynamics of the arterial and venal blood flow is monitored in certain time intervals with the help of non-invasive ultrasound Doppler scan.

I am informed about the examination and rare but possible complications (I have been provided written instructions about how to act).

I express my consent for the examination by signature.
